

Vello ProviderCard: Design Fidelity Audit

Component: ProviderCard (Maya Rivera), built with AI assistance from the Home screen reference (`image (1).png`), cross-checked against the real Vello Design System token files and component bundle.

Working component (guardrail-active build, the "after"):
<https://claude.ai/design/p/82fde247-6976-415f-b9a6-f69df091813a?file=Vello+Provider+Card.dc.html&via=share>

Earlier build (v1-v3, manual fixes, the "before"):

Token drift: found and fixed

Property	Was	Now	Token
Card padding	15px, hardcoded	20px	<code>card md scale</code>
Hover elevation	<code>--shadow-md</code> (one level too weak)	<code>--shadow-lg</code>	
Name text size	17px (off-scale)	18px	<code>--text-md</code>
Bio text size	13.5px (violates "never below 14px")	14px	<code>--text-sm</code>
Available badge	Custom coral/accent colors	Real success colors	<code>--success / --green-100 / --green-700</code>
Verified mark	Hand-built circle, hardcoded hex, no shape meaning	Real <code>VerifiedMark</code> component	shield shape, <code>--green-600</code> , <code>--paper rim</code>

Left as documented, not "fixed": the walk-time chip's own styling and the 13px icon size. Both are open questions, not confirmed drift (see below).

Worth noting: I checked several of these values against the real prototype source, not just the docs, and confirmed the walk-chip's padding and the card's 14px gap are exact matches to the real, off-token production code. That raised a real tradeoff: fixing card padding to the token scale (15px to 20px) made the build more token-correct but less pixel-faithful to the actual reference, since the reference itself doesn't follow its own scale.

Accessibility: found and fixed

Issue	Reference	Fix
Card's outer wrapper was a <code>div</code> with <code>cursor:pointer</code> only, mouse-clickable but not keyboard-reachable	WCAG 2.1.1 Keyboard (Level A)	Rebuilt as a real <code><button type="button"></code> ; Tab reaches it, Enter/Space activates it

Issue	Reference	Fix
Verified mark had no <code>role</code> , <code>aria-label</code> , or <code>title</code> , invisible to screen readers	WCAG 1.1.1 Non-text Content; docs: "the mark exposes a title"	Real <code>VerifiedMark</code> component ships <code>role="img"</code> + <code>"Background-checked"</code> label automatically
Verified mark was a plain circle, so the shape-only signal was gone	Docs' own DON'T: "never substitute a plain green dot or check for the shield"	Real <code>VerifiedMark</code> renders the actual olive shield + cream check
Contrast: walk-time chip text on its background	WCAG 1.4.3 AA (4.5:1)	Checked: 5.69:1 , passes, no fix needed

Guardrail (Practice 5.4): measurable before and after

I wrote `guardrail.md`, tying every rule back to Vello's "**trust scales locally**" bet, not just style preference: real tokens only, no invented values or assets, a real a11y baseline, "compare against reference before done."

I regenerated the card from a **plain instruction** (no hand-corrected spec) with the guardrail active, and the result matched the reference on the first try. Padding, shadow, text sizes, badge color, and the verified-mark's shape, label, and keyboard bugs (all things that needed manual, one-by-one fix instructions in the earlier rounds) were correct without any follow-up this time. It also flagged two new honest gaps on its own instead of guessing (see below).

Unresolved: questions for the designer

1. **Layout conflict:** the documented `ProviderCard` places rating under the name and price in its own column; the Home screen places rating next to the distance pill and price above it. I built from the Home screen. Which should new components follow?
2. **No icon-size token or scale exists** anywhere in the system (Tag=16px, card chevron=15px, this icon=13px, all independent). Left at 13px and flagged, rather than guessing a fix.
3. **No container-width token matches the reference card's width.** Used a token-derived value (`calc(var(--container-app) + var(--space-12))`) instead of a raw guessed px.
4. **Three items observed on the original reference screen itself** (not introduced by the AI): the tag/chevron crowding, the price line's spacing, and the walk-time chip showing both an icon and the word "walk" (redundant). Intentional, or worth fixing at the source?
5. **Should the card be rebuilt on the real `ProviderCard` component**, now that it's accessible via the bundle? Declined for now, since it would silently resolve question #1 instead of leaving it open.
